

Documenting C++ with Doxygen and Sphinx - Exhale

Rohit Goswami · 2020-09-22 · documentation · workflow · cpp · sphinx · doxygen

This post outlines a basic workflow for C++ projects using Doxygen, Sphinx, and Exhale.

Background

My project proposal for documenting [Symengine](#) was recently accepted for the Google Summer of Docs initiative. In the past I have been more than happy to document C++ code using **only** [Doxygen](#) (with [pretty fantastic results](#)), while keeping example usage separate ([d-SEAMS wiki](#)). Though this is still a feasible method, a monolithic multi-project setup might benefit from [Sphinx](#), which is what will be covered.

Goals

A couple of goals informed this approach:

- We expect our documentation to link to the source files
- We expect a lot of Python developers to contribute
 - Hence Sphinx
- We would like to write `.ipynb` files into the docs
 - Another reason to use Sphinx (via [MyST{NB}](#))

Folder Structure

```
tree -d $prj/ -L 2
```

```
•
├── docs
│   ├── Doxygen
│   └── Sphinx
├── nix
│   └── pkgs
├── projects
│   └── symengine
└── scripts
```

8 directories

Essentially we have a `scripts` directory to store basic build scripts, and two kinds of documentation folders.

Basic Doxygen

The `doxygen` setup is beautifully simple:

```
cd docs/Doxygen
doxygen -g
# Easier to edit
mv Doxyfile Doxyfile.cfg
```

Since `Doxyfile` should be updated by subsequent versions of `doxygen`, it is best to separate the project settings. We will therefore modify some basic settings in a separate file

```
touch Doxyfile-prj.cfg
vim Doxyfile-prj.cfg # or whatever
```

Edit the file to be (minimally):

```
@INCLUDE                = "../Doxyfile.cfg"
GENERATE_HTML            = NO
GENERATE_XML             = YES
XML_PROGRAMLISTING      = NO

# Project Stuff
PROJECT_NAME             = "myProject"
PROJECT_BRIEF            = "Dev docs"
OUTPUT_DIRECTORY        = "../gen_docs"

# Inputs
INPUT                   = "../../projects/symengine/symengine"
RECURSIVE               = NO
```

With this we will now be able to obtain the `xml` files for the rest of this setup.

Exhale

For our first attempt, we will focus on the automation of Sphinx using the [exhale tool](#).

```
# Basic setup
poetry init
poetry add exhale breathe
```

Now we can generate the basic Sphinx structure.

```
# Separate source and build
sphinx-quickstart --sep --makefile docs/Sphinx \
  --project "My Proj" \
  --author "Juurj" \
  --release "latest" \
  --language "en"
```

This allows us to generate the Sphinx documentation we require, with some changes to the `docs/Sphinx/source/config.py` file (lifted from the [exhale documentation](#)):

```

extensions = [
    'breathe',
    'exhale',
]

# -- Exhale configuration -----
# Setup the breathe extension
breathe_projects = {
    "My Proj": "../..../Doxygen/gen_docs/xml"
}
breathe_default_project = "My Proj"

# Setup the exhale extension
exhale_args = {
    # These arguments are required
    "containmentFolder":     "./api",
    "rootFileName":          "library_root.rst",
    "rootFileTitle":         "Library API",
    "doxygenStripFromPath":  "..",
    # Suggested optional arguments
    "createTreeView":        True,
    # TIP: if using the sphinx-bootstrap-theme, you need
    # "treeViewIsBootstrap": True,
}

# Tell sphinx what the primary language being documented is.
primary_domain = 'cpp'

# Tell sphinx what the pygments highlight language should be.
highlight_language = 'cpp'

```

We also need to add the output to the `index.rst` use the following:

```

.. toctree::
   :maxdepth: 2
   :caption: Contents:

   api/library_root

```

At this point we are ready to manually build our documentation.

```

cd docs/Doxygen
doxygen Doxyfile-prj.cfg
cd ../Sphinx
make html

```

This is still pretty cumbersome though. We can view our documentation in a more pleasant manner with `darkhttpd`.

```
darkhttpd docs/Sphinx/build/html
```

With this we now beautify the documentation (with the [sphinx_book_theme](#)):

```
poetry add sphinx-book-theme
```

We need to set the theme as well (in the Sphinx `config.py` file):

```
html_theme = 'sphinx_book_theme'
```

This leads to some pretty documentation.

Conclusions

At this point, we have a basic setup, which we can tweak with a bunch of themes, and/or different parsers, but this is still pretty rough around the edges. However, a caveat of this setup is that the actual contents of the source are not visible in the generated documentation. [In the next post](#), we will look at automating this setup for deploying with Travis.
