

Replacing git-subrepo with josh-filter

Rohit Goswami · 2025-08-12 · todo · workflow · tools

To initialize (with `single` to get a clean history in the current repository):

```
→ git remote add hzeon git@github.com:HaoZeke/e0n
→ git fetch hzeon doCIIdimer
  josh-filter ':prefix=subrepos/e0n' FETCH_HEAD --single
  git merge --allow-unrelated FILTERED_HEAD
```

Changes can be made within the sub-repo.

```
echo "blah" > subrepos/e0n/blah
git add subrepos/e0n/blah
git commit -m "blah"
```

When changes are to be pushed back upstream / to another branch..

```
git fetch hzeon doCIIdimer
josh-filter ':subrepos/e0n' HEAD --update FILTERED_HEAD
git push hzeon FILTERED_HEAD:refs/heads/dotry
```

Which works since `josh-filter` allows for inverse operations and generates commits reproducibly. Personally I find this easier to grok than the many thousands of `bash` which makes up `git-subrepo` but this is debatable.
