

Jupyter data helpers

Rohit Goswami · 2024-04-15 · devenv · jupyter · python

Often my notebooks are organized with respect to `GITROOT`, so this snippet makes for an easy way to construct relative paths.

```
gitroot = Path(subprocess.run(["git", "rev-parse", "--show-toplevel"],
                              check=True,
                              capture_output=True).stdout.decode("utf-8").strip())

# Usage
exdata = gitroot / "data" / "very_important_folder"
```

For packages which demand string only paths, another helper can be used in tandem.

```
def getstrform(pathobj):
    return str(pathobj.absolute())
```

Along with a context manager for running commands in a particular directory (kanged from my `f2py` utilities):

```
@contextlib.contextmanager
def switchdir(path):
    curpath = Path.cwd()
    os.chdir(path)
    try:
        yield
    finally:
        os.chdir(curpath)
```

EDIT: These are now part of my `pycrumbs` (aka `pycrumpets`) helper library..
