Background

I recently had the opportunity to take part in an AMA (ask me anything) session for the CS106A students on Machine Learning for the Physical Sciences. This is a post about the technical issues, and also includes a video if you read through.

Zoom and LosslessCut

Zoom recordings are one of the nicer ways to deal with switching windows and screen sharing, especially after fixing the [dark screen glitch](#). However, though [LosslessCut](#) works really well to get cut-points, exporting and merging the file into one caused a bunch of glitches.

Enter Handbrake

To not beat around the bush, the solution was to simply encode the Zoom recording with [Handbrake](#) before using LosslessCut[^fn:1]. Since the conversion takes a while, it is also neat to note that you can directly export the cut points made with LosslessCut on the original video, then import them onto the newly encoded file.

Conclusions

I am not really sure how this will turn out, but it is a useful thing to keep in mind. The introductory video turned out to be:
