

precommit selections

Rohit Goswami · 2025-07-26 · regex · precommit

`pre-commit` accepts `exclude` keys which take `python` [regular expressions](#), typically designed with [regex101](#). For example:

```
exclude: |
  (?x)(
    thirdparty| # vendored
    xtb.h| # vendored
  )
- id: clang-format
  name: clang-format
  entry: clang-format
  language: system
  types_or: [c, c++, cuda]
  args: ["-fallback-style=none", "-style=file", "-i"]
```

While it is especially useful for tools which don't have ignore flags, as a convention:

- Use a globally defined `exclude`
 - Explain the exclusion with a comment
- Fine-tune with per-hook `types_or` (or even `files`)
 - Additional `exclude` keys may be used as well
